3 Preliminary Results

3.1 Measurements

A dual-stacked user when attempting to connect to a dual-stacked service traditionally prefers connecting over IPv6. This is because in POSIX systems, the internal domain name resolution system call `getaddrinfo(...)` [3] returns the list of addresses in an order that prioritizes an IPv6-upgrade path [1]. The dictated order can dramatically reduce the application responsiveness in situations where IPv6 connectivity is broken. This is because, the attempt to connect over an IPv4 address will take place only when the IPv6 connection attempt has timed out, which can be in the order of seconds.

This noticeable degraded user experience can be subverted by making applications apply the happy eyeballs algorithm [5]. The algorithm recommends that a dual-stacked application try resolving a dual-stacked service for both IPv4 and IPv6 addresses at once. If the resolver returns both addresses, the application must try a TCP `connect(...)` to both the resolved addresses and pick the one that completes first.

In this pursuit, to determine whether applications will use IPv4 or IPv6 on a dual stacked service, we developed `happy`, a simple TCP happy eyeballs probing tool. It uses non-blocking `connect(...)` calls to establish concurrent connections to a number of possible endpoints of a service. The tool does not check whether the endpoints of a given target all provide the same service. Hence, it is possible to impact the results by setting up fake servers that do not provide the service

tested and which are designed and deployed with the only purpose to provide fast connection setup times.

We have cross-compiled `happy` for the OpenWRT [2] platform. As a result, the tool can now be run on widely deployed SamKnows probes [1], and the collected measurement data can be further analysed. In order to ascertain the value in this exercise, we prepared an internal test-bed of multiple measurement points. The measurement points have different flavors of IPv4 and IPv6 connectivity ranging from native IPv4, native IPv6, 6in4, Teredo [4] and tunnelled IPv4.
